reset-o requires 7 to 8 hours per week of patient engagement for 90 days. each patient will receive a prescription for reset-o, including a starter kit, to be taken home and self-administered by the patient. the kit includes the reset-o application, a personal identification number (pin), a reset-o card to record when reset-o has been taken, and a card to record the date and time of each reset-o dose.

the reset-o treatment is a self-administered, 12-week, home-based program, prescribed by a licensed physician. reset-o is not intended to reduce the frequency or duration of in-person therapy, and is not intended to replace the need for ongoing medication management. yes, the board is powered from a 13.8v lipo battery. the board does not have a resettable switch. the board has a "momentary" reset switch that is held down by the battery for about a second, allowing the board to time out. the reset switch is just not connected to anything. (i did that, by using the wdt approach, and the board got stuck; i'm even unable to program the original code with pololu usb programmer. unfortunately, the board is battery powered and designers did not provide a reset button, therefore it seems i'm in a big trouble. did i miss something, or there are another way to put it to work again) you are missing a few important details regarding the reset. you need to understand that there is no such thing as a program memory location that is ready to run, it is all volatile memory, meaning that it is just "data" that is pre-allocated for the program's needs. this means that the data you write into this memory location is considered volatile and can be changed. memory location 0 is mapped to flash memory, and the address 0 is used to read from flash, that is why the reset will make the board go to a "factory default state", and the image you are loading into memory location 0 is the factory default image. if you want to have a function associated to address 0 you need to program the address in your image.
